

High Energy Astrophysics Experiments In The Laboratory & On Supercomputers*

*Edison Liang
Rice University*

*Collaborators: Rice students & postdocs plus
UT Austin, LANL, LLNL, UCUI, OU*

UHCL Talk, February 2014

** Work supported by NSF, DOE & NASA*

made possible by recent advances in
High Energy Density Physics

HPC

EXAMPLES:

Gamma-Ray Bursts

Laser-Generated Relativistic Shocks and
Fireballs

Black Hole Annihilation Flares

Laser-Generated Pair-
Plasmas

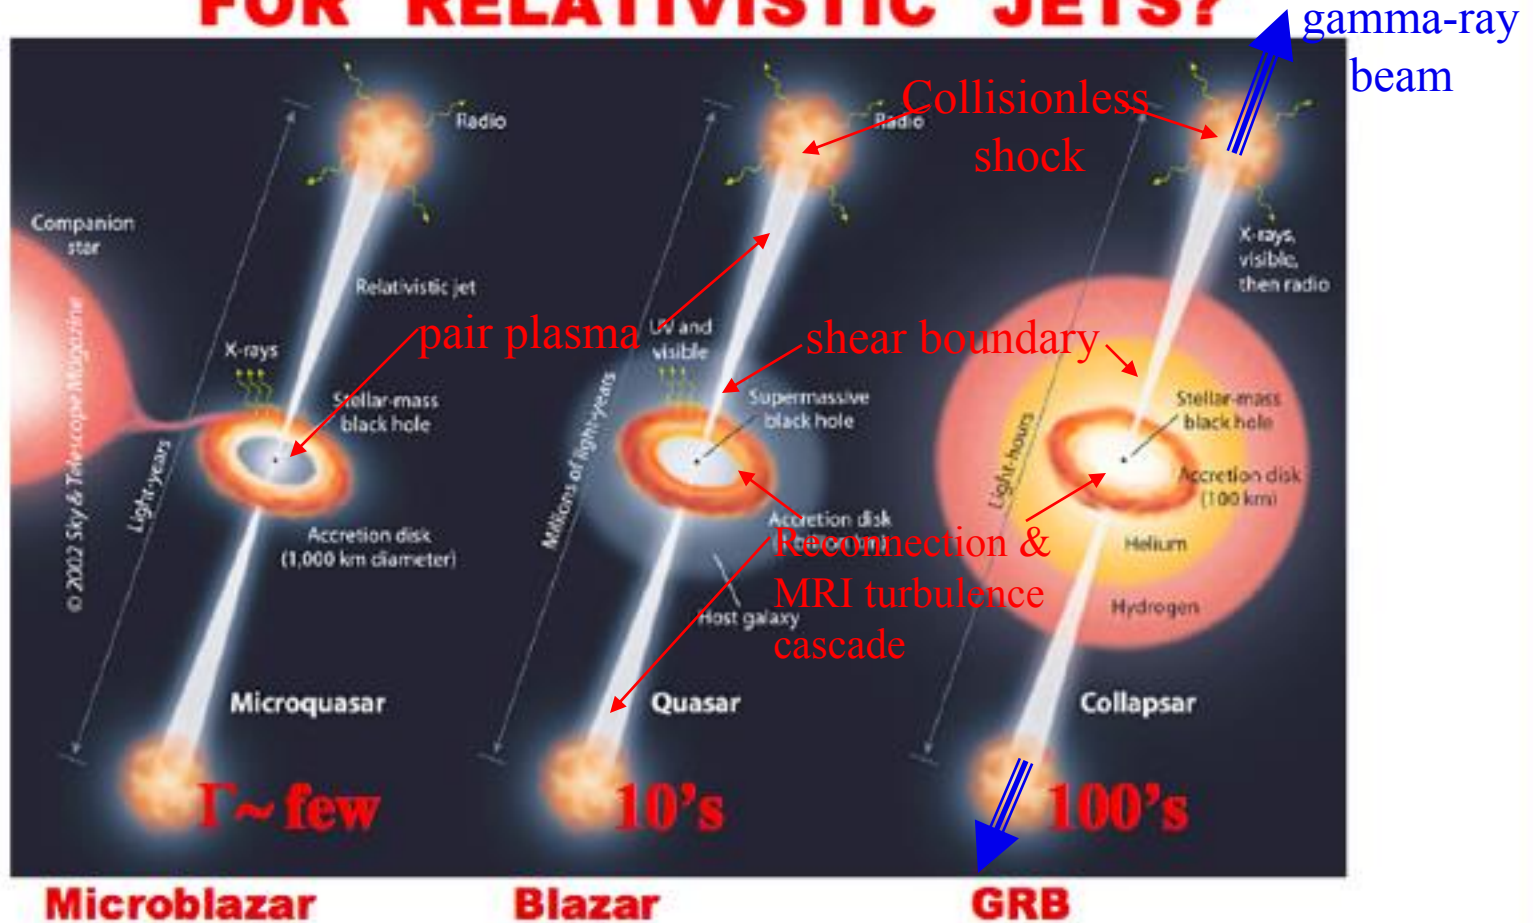

Sample HEA processes accessible
using relativistic laser experiments

1. e^+e^- Pair plasmas
2. Intense X-Gamma-ray Environments \sim GRBs
3. Collisionless Shocks & Shear Flows
4. $>10^9$ G B-fields Generation
5. Magnetic Reconnection
6. Poynting Flux & Particle Energization

Plus many others under consideration

Lab experiments cannot reproduce global features. But they can mimic the local physical processes and their radiation output

A UNIVERSAL MECHANISM FOR RELATIVISTIC JETS?

(Mirabel & Rodriguez; Sky & Telescope, May 2002)

Important Issue: what are the “scalable” processes & phenomena?

Phase space of laser plasmas overlap some relevant relativistic astrophysics regimes

Many new 0.1-1 kJ-class PW lasers are coming on line in the US, Europe and Asia

mirror

QuickTime™ and a
TIFF (Uncompressed) decompressor
are needed to see this picture.

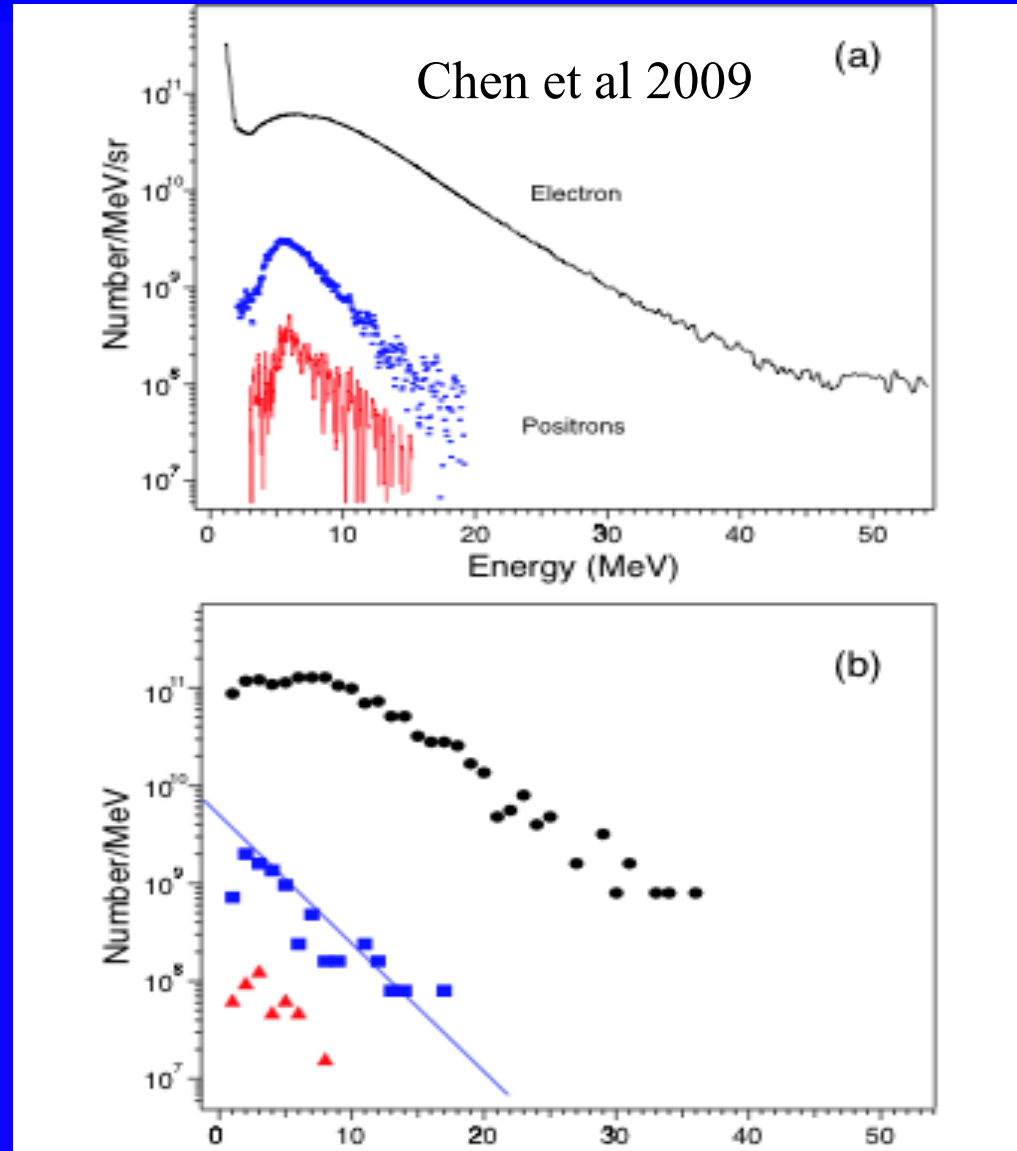

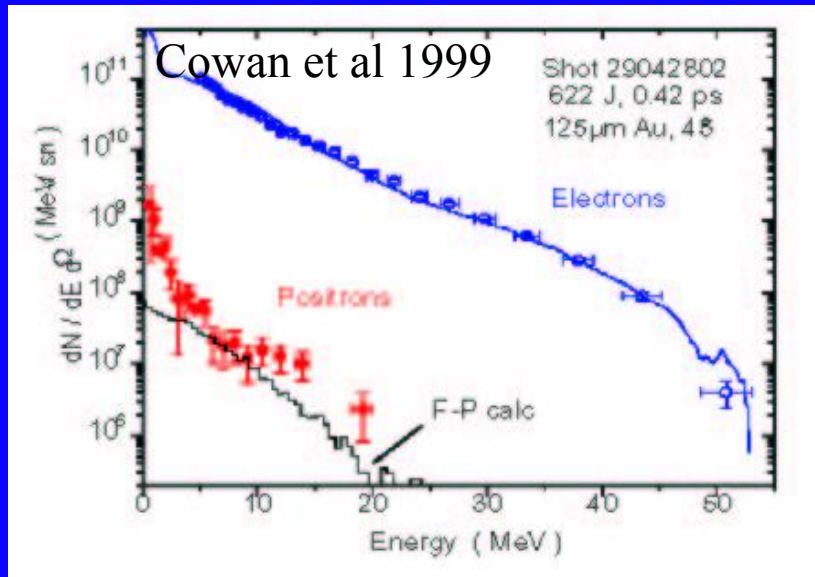

Ultra-intense laser is the most efficient tool to make e^+e^- pairs ($mc^2 \sim 1\text{MeV}$) in the laboratory

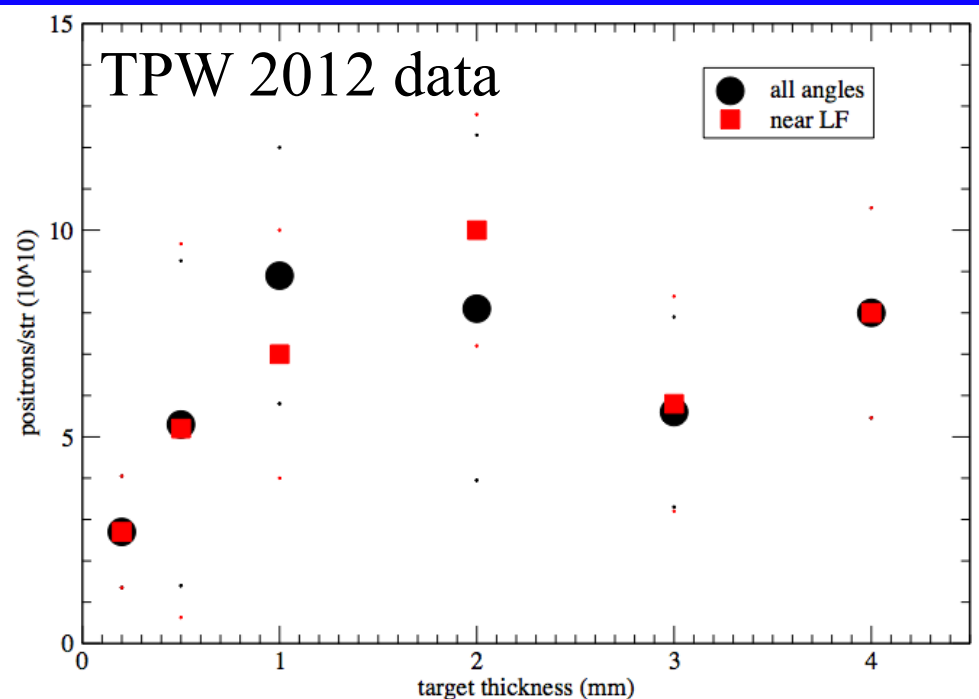

Lasers with intensity $> 10^{19} \text{W}\cdot\text{cm}^{-2}$ couple 10-50% of their energy to “hot electrons” with $kT_e > \text{MeV}$.

Laser pair creation was first demonstrated by Cowan et al in 1999 and greatly improved by Chen et al (2009, 2010) using laser intensities \sim few $\times 10^{19}$ - 10^{20} W.cm $^{-2}$.

in 10 years the e^+/e^- ratio has increased by ~ 100

Measured e^+e^- pair yield follows same trend as theory predictions

kT_e

QuickTime™ and a Graphics decompressor are needed to see this picture.

(Henderson et al 2011)

Intense lasers create intense flux of >MeV gamma-rays.

gamma-ray output $\sim 5\text{-}10\%$ of Laser Energy, with beam angle $\leq 15^\circ$.

Maximum γ -density \sim inside the GRB.

Total γ -fluence \sim ISM at 10 pc from a GRB.

1. Interaction of pairs with gamma-rays and strong-B fields
2. Interaction of gamma-rays with ISM, e.g. dust grain destruction with observable IR signatures.

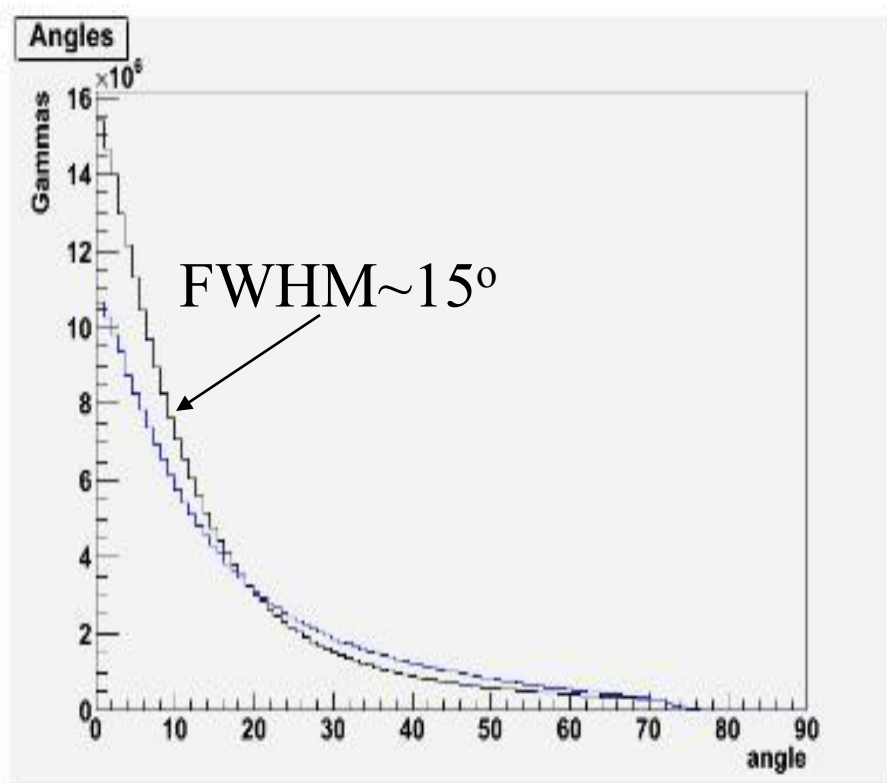

Figure X: Gamma Yield Versus Thickness. The GEANT4 Monte-Carlo simulation used the incident electron spectrum seen in figure X.

Collisionless Shocks are ubiquitous in the universe

Tycho SNR Ia

Cas-A SNR IIb

Collisionless Shocks likely Acceleration Sites for Cosmic Rays:
How do they efficiently generate magnetic fields and relativistic particles?

Creation and Diagnostic of Collisionless Shocks using lasers are very challenging, but great progress has been made in the past few years by the ACSEL team

Expt at Omega Laser 3ω Drive Beams

density and temperature data are consistent with theory predictions for collisionless shocks

Discovery of self-organized B-fields was unexpected and most exciting. Such fields may be important to particle acceleration in shocks.

Figure 2: Side-view time sequence of proton images showing the evolution of self-organized electromagnetic field structures.

Future
Ideas

Laser-created Dense electron/Pair Jets provides new opportunity on Relativistic Shocks

Fig.4 Artist conception of relativistic shock launched by head-on collision of two $e+e-$ pair jets created by two high-energy PW-class lasers irradiating mm-thick gold targets.

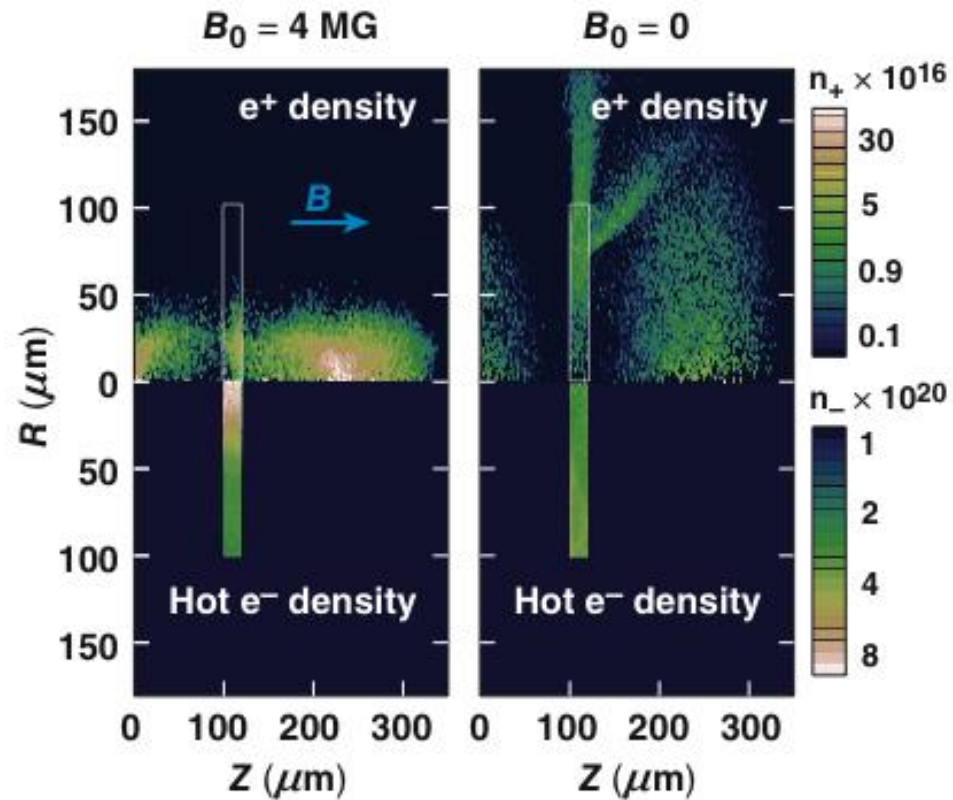

relativistic shear boundary layer may be formed by injecting laser-created relativistic e+e- jet into a low density foam

(adapted from picture courtesy of Wilks)

shear boundary layer may be easier to form, observe and diagnose than collisionless shocks

Laser-coupled Helmholtz Coils can generate vacuum axial $\mathbf{B} \sim 10^7 \text{G}$.
It can be used to confine e^+e^- pair plasma to study pulsar & GRB.

Physics of superstrong B can also be studied in the lab using intense lasers: Measured magnetic fields inside laser targets are now approaching $\sim 10^9$ gauss

Magnetic reconnection and current sheets dissipation can be studied using two adjacent lasers

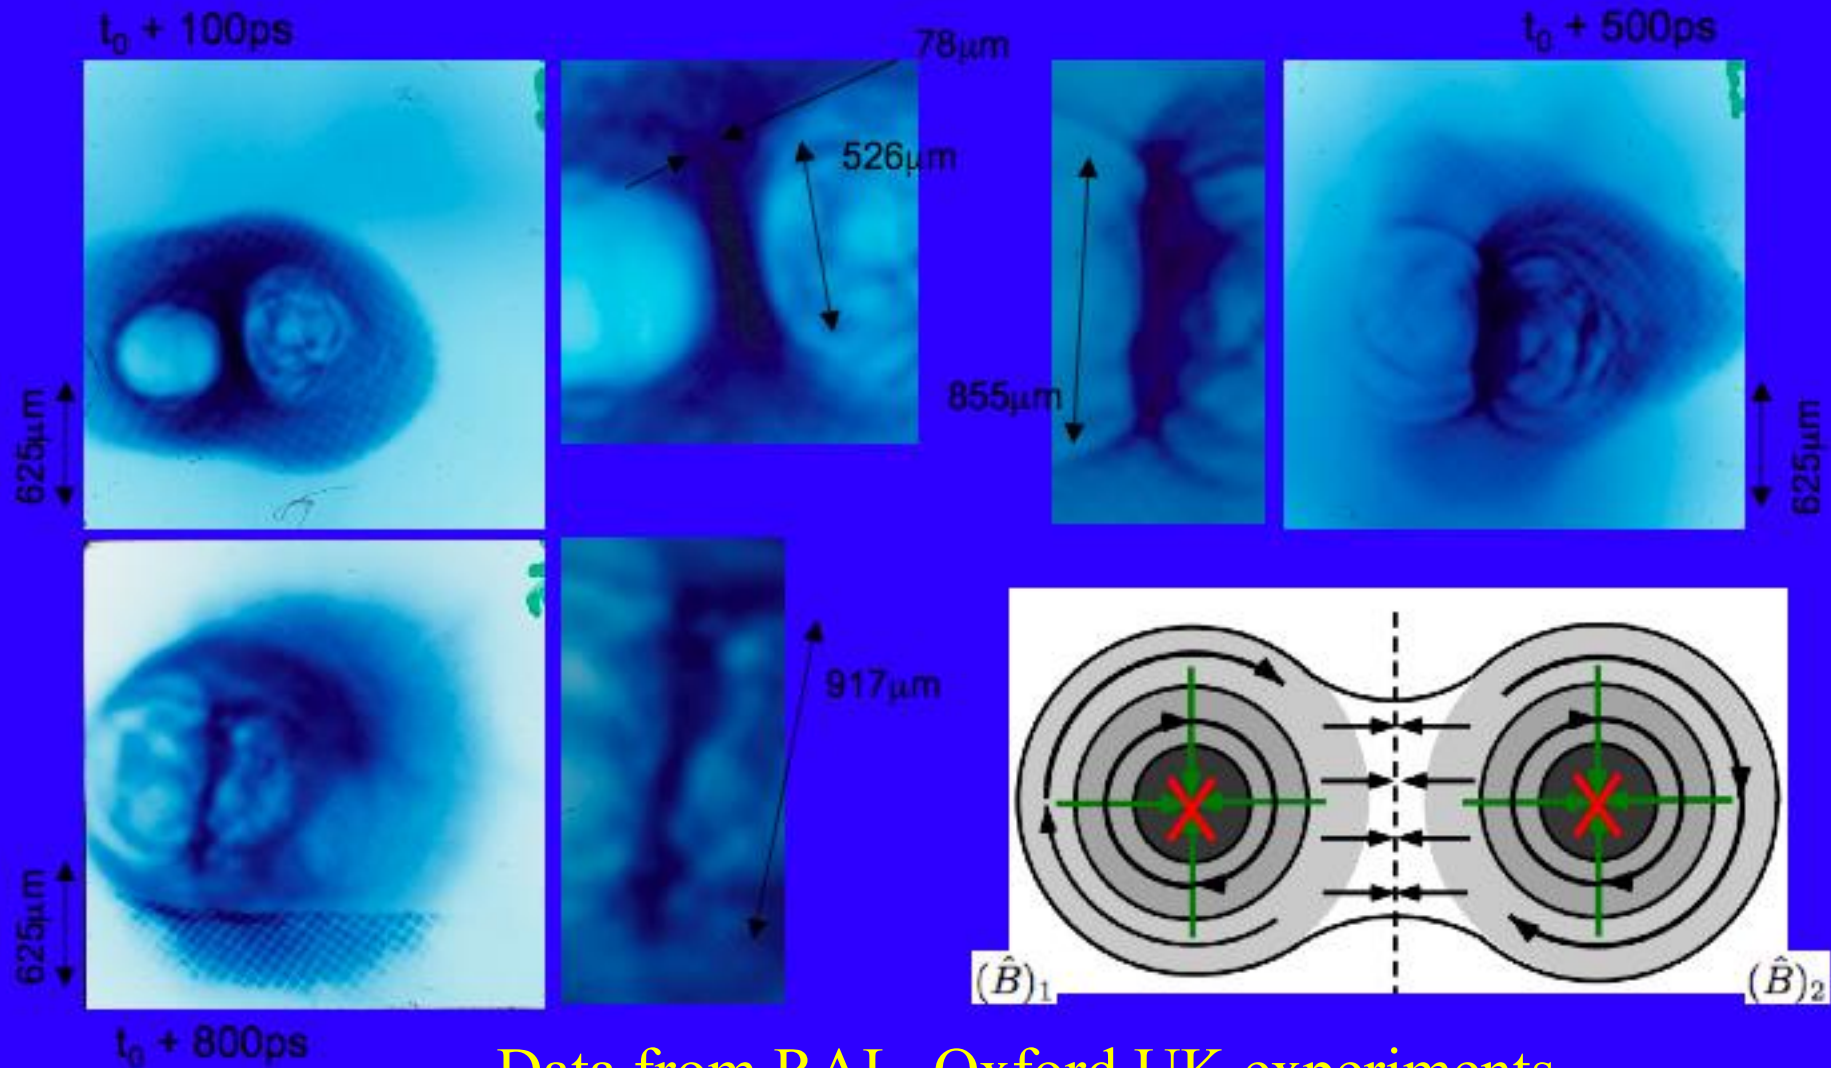

Long-pulse (ns) solid target interactions
Magnetic field generation: dual beam geometry

Reconnection Physics have been studied using two lasers

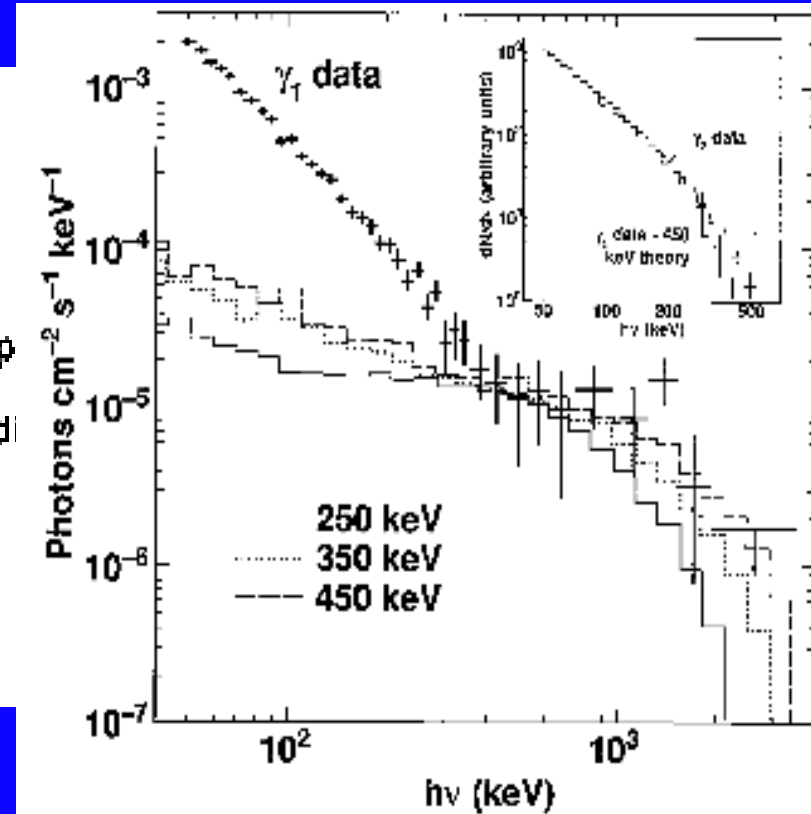

Plasma dynamics: Al target

Rear projection proton imaging (fields ~ 1 MGauss)

Data from RAL, Oxford UK experiments.

2D model of a pair-cloud surrounded by a thin accretion disk to explain the MeV-bump of Cyg X-1

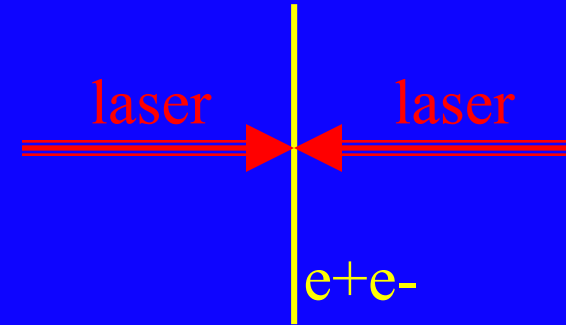

Double-sided irradiation plus sheath focusing may provide astrophysically relevant pair “fireball” in the center of a thick target cavity: ideal lab for GRB & BH γ -flares

Thermal equilibrium pair plasma and BKZS limit may be replicated if we have multiple ARC beams staged in time sequence.

Pulsar Wind = Linearly Polarized EM Wave but Loaded with “overdense” Pair Plasma. How to do this with lasers?

QuickTime™ and
Apple's QuickTime
are needed to see this picture.

$t\omega_e = 540$

$t\omega_e = 14400$

colliding laser pulses can load overdense e+e- plasma and accelerate them

In Astrophysics, we need multi-physics, multi-scale Computer Simulations that Include:

1. MHD for global dynamics
2. Radiation Transport for observable signatures
3. GR for strong gravity effects
4. Particle-in-Cell (PIC) Simulations for field generation, dissipation and particle energization.

*Our group is involved in all four types of simulations
and efforts to link simulations of different types*

High-energy emission of low-luminosity black hole such as SgrA* exemplifies accretion which requires energization above the level predicted by thermal SSC model with only e-ion coulomb coupling
